

**Exercise 1.** Let  $ABC$  be a triangle and let  $E$  be an ellipse tangent to sides  $AB, BC, CA$  at points  $C', A', B'$  respectively. Show that  $AA', BB', CC'$  are concurrent.

**Exercise 2.** Suppose that an affine transformation sends a circle  $C$  to itself. Show that it sends the center of  $C$  to itself.

**Exercise 3.** Let  $E$  be an ellipse intersecting triangle  $ABC$  in six points  $A_1, A_2, B_1, B_2, C_1, C_2$  so that the points  $A_1, A_2$  are on the segment  $BC$ , points  $B_1, B_2$  are on the segment  $CA$ , points  $C_1, C_2$  are on the segment  $AB$ . Prove that if  $AA_1, BB_1, CC_1$  are concurrent, then  $AA_2, BB_2, CC_2$  are also concurrent.

**Exercise 4.** Let  $a, b, c$  be three vectors in the plane with the property that  $\alpha a + \beta b + \gamma c = 0$  for some scalars  $\alpha, \beta, \gamma$ . Prove that these vectors can be transformed to unit length vectors by an affine transformation if and only if there exists a triangle with side lengths  $|\alpha|, |\beta|, |\gamma|$ .

**Exercise 5.** Let  $E$  be an ellipse and let  $A, B$  be distinct points on it. Show that there are exactly two affine transformation that send  $E$  to itself and send the point  $A$  to point  $B$ .

**Exercise 6.** Given an acute triangle  $ABC$  prove that the perimeter of the triangle  $A'B'C'$  whose vertices are the feet of the altitudes of  $ABC$  is less than twice the length of any height.

**Exercise 7.** Let  $ABC$  be a regular triangle ( $AB = BC = CA$ ). Show that for every point  $P$  inside the triangle the sum of distances from  $P$  to the sides  $AB, BC$  and  $CA$  is the same.

**Exercise 8.** 1. Let  $l$  be a line and let  $A$  and  $B$  be two points lying on different sides of it. Assume that the quantity  $|PA - PB|$  is largest at point  $P$  among all points  $P$  on  $l$ . Let  $Q$  be a point on  $l$  that is different from  $P$ . Prove that  $\angle APQ = \angle BPQ$

2. Use part 1 to explain why for a tangent line  $l$  to hyperbola given by the relation  $PA - PB = \text{const}$  the following holds: if  $Q$  is a point on  $l$  distinct from  $P$  then  $\angle APQ = \angle BPQ$

**Exercise 9.** Consider a triangle  $ABC$ . Assume that angles at the vertices  $A, B$  are smaller than  $45^\circ$ . Let  $P$  be a point inside the triangle. Give an explicit construction that produces points  $A' \in BC, B' \in CA, C' \in AB$  such that the sum  $PA' + A'B' + B'C' + C'P$  is the smallest possible.

**Exercise 10.** *Let  $ABC$  be a triangle with angles  $\angle A = 30^\circ$ ,  $\angle B = 60^\circ$ ,  $\angle C = 90^\circ$ . For what points  $P$  inside the triangle is the sum  $PA' + \sqrt{3}PB' + PC'$  the largest, where  $A', B', C'$  are orthogonal projections of point  $P$  onto the sides  $BC, CA, AB$  respectively. For what points  $P$  inside the triangle it is the smallest?*
